The production of food in all forms results in emissions of greenhouse gases. Carbon footprints are a measure quantifying the greenhouse gas emissions that result from the production of any given food item, or for a given product, activity or industry. A carbon footprint refers to all the greenhouse gases’ potential to trap heat in the earth’s atmosphere. For beef production, a carbon footprint refers to CO₂ equivalent emissions per unit of beef.

Figure 1. Greenhouse gas emissions from beef production expressed as kg of CO₂ equivalents per gram of protein.
Source: Herrero et al., 2013 PNAS 110: 20888-20893

Comparing the U.S. beef industry’s carbon footprint to other nations is challenging for two main reasons:
1. Methodologies used by different published studies to calculate carbon footprints within and across nations vary in ways that can influence their estimated carbon footprint.
2. Efficiency of practices in how beef cattle are raised across countries vary greatly (i.e., productive use of resources to maximize the total amount of beef produced), and efficiency is a key driver of beef’s carbon footprint.

To overcome these challenges, one can examine the results from individual studies using the same methodology to estimate CO₂ equivalent emissions across the wide range of beef production systems found in the world.

In two recent analyses of global livestock systems¹², North American beef production systems (including the U.S.) were found to have some of the lowest carbon footprints. As seen in Figure 1, when CO₂-equivalent emissions are expressed per kg of protein, the U.S. and other developed nations have lower carbon footprints (10 to 50 times lower), compared to many...
nations in sub-Saharan Africa and the Indian subcontinent. The lower CO$_2$ equivalent emissions per kg of protein for beef production systems in the developed world are driven by higher quality (more digestible) feeds, lower impacts of climate stress (heat) on animals, improved animal genetics, advancements in reproductive performance and the reduced time required for an animal to reach its slaughter weight compared to regions with higher carbon footprints. Combined, all of the above-mentioned factors drive improvements in the efficiency of beef production, while decreasing the use of natural resources and production of environmental emissions per unit of beef produced. Furthermore, it is these factors that are responsible for reducing the U.S. carbon footprint of beef by an estimated 9 to 16 percent from the 1970's to the present day. Using management techniques and technologies developed through scientific research is key to achieving improvements in beef production efficiency and further reducing beef’s carbon footprint.

Summary

The U.S. beef industry has one of the lowest carbon footprints in the world due to cattle genetics, the quality of cattle feeds, animal management techniques and the use of technology.
