Green Composite Panels Manufactured from Eastern Redcedar

Salim Hiziroglu  
FAPC Wood Products Specialist

Onur Ulker  
Assistant Professor, Kirikkale University, Turkey

Wood-base composite panels including particleboard and fiberboard are widely used for many applications, such as underlayment for carpeting as core material, paneling, furniture and cabinet manufacture. The majority of particleboard panels is produced using 10 to 15 percent formaldehyde-based adhesives primarily urea formaldehyde (UF) as a binder for typical production. This fact sheet summarizes some of the main aspects of particleboard manufactured from Eastern redcedar using non-toxic modified starch as green binder.

It is a known fact formaldehyde-based adhesives are considered as a dangerous substance due to formaldehyde emission and linked to health problems from both short- and long-term exposure. Therefore, there is a movement to find alternative green adhesives that eliminate formaldehyde emission from the panels. Modified starch is one such potential environmentally friendly binder.

Eastern redcedar (Juniperus virginiana L.) is considered an invasive species encroaching in the Great Plains and one of the predominant invasive woody species in the United States. Eastern redcedar quickly replaces the native grasslands, adversely influencing the diversity of plants, birds and small mammals in Oklahoma. With an estimated growing rate of 380 hectares per day resulting in a significant adverse impact on the overall ecological system. Negative impacts of the encroaching of Eastern redcedar include the loss of native plants and animals, reduction of forage production and livestock handling, impacts on soil hydraulic properties and increased risk of wildfires. As an invasive species Eastern redcedar could be considered as a viable raw material to manufacture particleboard panels.

In a past study, experimental composite panels from whole-tree chipped redcedar were manufactured using UF adhesive, resulting in both satisfactory physical and mechanical properties. Since there is no or little information on properties of particleboard panels made from Eastern redcedar using modified starch, this study attempted to produce initial data on properties of such value-added panel products. When one considers the combination of this resource with a green-based adhesive, such invasive species can be converted into value-added panel products so an important ecological problem can be solved with an environmentally friendly approach.

Manufacture of Experimental Particleboard Panels Using Starch

Commercially produced Eastern redcedar particles supplied by a local producer in Oklahoma were used to produce experimental panels. Dried particles having a moisture content of 3 percent were classified into fine and coarse sizes on a 20-mesh and 60-mesh screen, respectively. Coarse particles were used for the core layer of the three-layer particleboard, while the fine particles were used for the surface layers of the panel. Corn starch, along with glutardialdehyde (GDA) was mixed manually with the particles as binder for the panels. GDA is a colorless, oily liquid organic compound having the formula of CH₂(CH₂CHO)₂, which is widely used as a disinfectant agent for medical equipment.
No wax or any other additives were used in production of the samples. The ratio of the surface layer thickness to the total thickness of a panel known as the shelling ratio was 0.30 for all specimens. Figures 1 and 2 illustrate the overall process of panel manufacture and untrimmed panel, respectively. Hand-formed mats were pressed in a computer-controlled press, an Erie Mill & Press Company Inc., 24-inch by 24-inch 270-ton press using a pressure of 5.5 MPa at a temperature of 180 degrees Celsius for 20 minutes. A total of 15 panels were made using each of the three density levels. Panels were conditioned in a conditioning room, having 65 percent relative humidity and a temperature of 20 degrees Celsius for two weeks before samples were cut for different tests based on American Society for Testing Material D1037-12.

**Initial Test Results of the Samples**

Overall bending and internal bond strength of the samples were determined to be within the expected range as compared to those of typical commercially manufactured particleboard panels from other species. Modulus of elasticity and internal bond strength values of the samples ranged from 344,263 psi to 640.337 psi and 63 psi to 132 psi, respectively. Water absorption and thickness swelling of the panels were relatively high. Panels made with 0.80 g/cm$^3$, 0.70 g/cm$^3$ and 0.60 g/cm$^3$ density levels had water absorption values of 164 percent, 160 percent and 153 percent, respectively. Corresponding thickness swelling values were 18 percent, 23 percent and 31 percent. Typical commercially manufactured particleboard would have within thickness swelling values ranging from 8 to 10 percent as a result of a 24-hour water soaking test. The main reason of dimensional instability of the samples can be related to very large hygroscopicity of starch as well as not using any wax as additives in the samples. Figure 3 shows thickness swelling of dry and water soaked samples for comparison purpose. Also, nonhomogeneous mixture of starch, as illustrated in Figure 4 taken by scanning electron microscope, would result in low dimensional stability of the panels.
Further information can be found in below references:

The Oklahoma Cooperative Extension Service
Bringing the University to You!

The Cooperative Extension Service is the largest, most successful informal educational organization in the world. It is a nationwide system funded and guided by a partnership of federal, state, and local governments that delivers information to help people help themselves through the land-grant university system.

Extension carries out programs in the broad categories of agriculture, natural resources and environment; home economics; 4-H and other youth; and community resource development. Extension staff members live and work among the people they serve to help stimulate and educate Americans to plan ahead and cope with their problems.

Some characteristics of Cooperative Extension are:
- It provides practical, problem-oriented education for people of all ages. It is designated to take the knowledge of the university to those persons who do not or cannot participate in the formal classroom instruction of the university.
- It utilizes research from university, government, and other sources to help people make their own decisions.
- More than a million volunteers help multiply the impact of the Extension professional staff.
- It dispenses no funds to the public.
- It is not a regulatory agency, but it does inform people of regulations and of their options in meeting them.
- Local programs are developed and carried out in full recognition of national problems and goals.
- The Extension staff educates people through personal contacts, meetings, demonstrations, and the mass media.
- Extension has the built-in flexibility to adjust its programs and subject matter to meet new needs. Activities shift from year to year as citizen groups and Extension workers close to the problems advise changes.

Some characteristics of Cooperative Extension are:
- The federal, state, and local governments cooperatively share in its financial support and program direction.
- It is administered by the land-grant university as designated by the state legislature through an Extension director.
- Extension programs are nonpolitical, objective, and based on factual information.
