Dietary Salt and Sodium

Janice R. Hermann, Ph.D., RD/LD
Nutrition Specialist

Dietary Salt
Sodium chloride, salt, contains 40% sodium and 60% chloride by weight. Some foods naturally contain sodium however, usually in small amounts. Some people add salt in cooking and at the table, but the majority of dietary salt and sodium comes from foods where salt has been added during processing or preparation.

Functions of Sodium
Sodium has many important functions in the body including:
- maintaining water balance
- maintaining acid-base balance
- transmission of nerve impulses
- regulating muscle contractions
- absorption and transport of some nutrients

Too Much Salt
Although sodium has important roles in the body, most people consume more sodium than they need. The Dietary Reference Intake (DRI) for sodium is 1,500 mg/day for people 19-50 years of age, 1,300 mg/day for people 51-70 years of age, and 1,200 mg/day for people >70 years of age. The Upper Level for sodium intake for adults is 2,300 mg/day. The Dietary Guidelines for Americans recommends people reduce daily sodium intake to less than 2,300 mg.

Sodium and High Blood Pressure
High sodium intake may contribute to high blood pressure in “salt sensitive” individuals. For these individuals, too much salt and sodium intake may be related to the development of high blood pressure. High blood pressure puts extra strain on the heart. This strain can lead to heart problems, including heart attack, stroke, and kidney failure. Most evidence suggests that individuals at risk for high blood pressure reduce their chances of developing this condition by consuming less salt and sodium and maintaining a healthy weight.

There is no way at present to tell who may be sodium sensitive or who may develop high blood pressure from consuming too much sodium. However, many health professionals recommend that the population as a whole should reduce sodium intake.

Sources of Sodium
- The saltshaker: Table salt is the most common source of sodium. A level teaspoon contains about 2,000 milligrams of sodium. You can reduce sodium in your food by not adding salt in preparation or at the table.
- Foods naturally contain sodium: All foods that come from animals contain some sodium, and some plants, such as beets, carrots, celery, and spinach contain more sodium than others.
- Processed foods: In general, processed foods provide the majority of sodium in the diet. Salt or other sodium compounds are added to food during preparation or processing for flavor or preservation. These foods include cured meats (hot dogs, bologna, sausage, bacon); pickled foods (pickles, olives, sauerkraut); canned vegetables; frozen peas and lima beans; salted snack foods (potato chips, crackers, corn chips); soy and other sauces; baking soda; baking powder; monosodium glutamate (MSG); and other seasonings.
- Drinking water: Soft water contains more sodium than hard water. In some areas of the country the drinking water may be high in sodium. Water softeners increase the sodium content of the water. Contact the local health department if you want more information on the sodium content of the water in your community.
- Medications: Many over-the-counter medications contain sodium. These include medications for indigestion, headache remedies, cough medicines, laxatives, as well as many others. Check the label of over-the-counter medications for sodium content.

Sodium on the Food Label
The Nutrition Facts Panel on food labels lists the number of milligrams of sodium per serving of food. The Nutrition Facts Panel also lists the percent Daily Value one serving provides for sodium based on a 2,000-calorie reference diet.

The following terms are used on food labels to describe the sodium content of foods.
- Sodium free: 5 mg or less sodium per serving
- Very low sodium: 35 mg or less sodium per serving
- Low sodium: 140 mg or less sodium per serving
- Reduced sodium: usual sodium level reduced by at least 25 percent
- Unsalted or no salt added: no salt added during processing; however, the product may still contain sodium

Salt and other sodium products are common food additives and food preservatives. Be a label reader and watch for ingredients containing sodium, such as:
- Monosodium glutamate - used to enhance food flavor
- Disodium phosphate - quick cook cereals and processed cheeses
- Sodium alginate - used in chocolate milk and ice cream; holds chocolate in suspension
- Sodium benzoate - a preservative
• Sodium hydroxide - used to process “Dutch Chocolate”
• Sodium propionate - inhibits molds in bread and cake

Sodium and Baby Food
As a parent, you should not add salt to baby’s food. Too much salt is a burden on your baby’s kidneys. Baby food manufacturers have reduced the salt in baby foods. If you prepare baby food at home, be certain you do not salt the vegetables or meats before or after pureeing. You should not puree those foods prepared for other family members if salt was added.

Sodium and Perspiration
Use regularly salted foods to replace sodium lost from perspiration. Normally, your body will adapt during perspiration so that you will not lose too much sodium. If you are healthy, a well balanced diet will give you enough sodium. However, sometimes you may need more salt if you are working under extremely hot conditions and sweating excessively. When that occurs, you should eat your regular diet with some salty foods and drink sufficient water, rather than taking salt tablets. Salt tablets contain much more sodium than the amount of sodium lost from perspiration.

Physicians and sports nutritionists do not recommend sweating off weight to meet a weight classification because this can cause stress to the heart and blood vessels and result in poor performance. You lose body water, not body fat when you sweat off weight over a period of several hours. Drinking water will quickly restore the weight loss. You should not lose weight by water and salt restriction but reduce your calories and increase physical activity to achieve about a one to two pound loss per week.

Salt Substitutes
Salt substitutes and “light” salts are not for everyone. Some substitutes contain ingredients that may be harmful for certain people. Check with your physician or dietitian before using them.

Suggestions for Lowering
Salt at Restaurants
• Call ahead and ask if the restaurant has special menus.
• Select single item, identifiable foods rather than combinations. Plain broiled meats, baked potato, and green salad can be ordered without salt. Ask for oil and vinegar to use on the green salad or carry your own dressing with you.
• Ask for a wedge of lemon and use lemon juice on your salad or other vegetables. Many restaurants use packets of lemon juice with a preservative containing sodium.
• Avoid gravies, sauces, catsup, and mustard. These are high in sodium.
• Choose fresh vegetables rather than cooked ones. Canned vegetables contain salt. Restaurants use salt and often monosodium glutamate to season cooked vegetables.
• Remove skin from chicken or turkey and order inside portions of roasts if possible. Ask that steak or chops be prepared without salt.

Healthy Choices to Lower Sodium through the USDA MyPlate Food Groups
Grain Group
• Read the Nutrition Facts Panel to compare the sodium content of cereals.
• Snack foods are typically high in sodium. There are lots of reduced sodium or no-salt-added snacks available.

Dairy Group
• Cheeses vary in sodium content, but tend to be higher in sodium than milk or yogurt.
• Processed cheeses, cheese foods, and cheese spreads contain more sodium than natural cheese. Reduced sodium cheeses are available.

Oils
• As a general rule, salad dressings and condiments are high in sodium.
